Clipping of a partially thrombosed giant PICA aneurysm associated with the anterior spinal artery

Gregory Glauser, Matthew Piazza, Ryan Dimentberg, Omar Choudhri

DESCRIPTION
This video 1 case presents some unique technical tenets for the microsurgical clipping of a giant posterior inferior cerebellar artery aneurysm. The patient described in this case was a 60-year-old woman with a history of coil embolisation of a left vertebral artery aneurysm. The patient presented with headaches and mild left-sided blurry vision, which remained after prior embolisation. Cerebral angiography (figure 1) demonstrated interval coil compaction with marked increase in the aneurysm base, measuring $9.8 \times 7.2 \times 4.0$ mm (figure 2). Alternative treatment options considered this patient included stent coiling, pipeline embolisation or left vertebral artery coil sacrifice. This case is valuable to the literature as it illustrates technical steps required for clipping of a large aneurysm using fenestrated clips and need for identification and preservation of anterior spinal artery.

Learning points
► This case demonstrates the usefulness of far lateral craniotomy with transcondylar exposure for large posterior inferior cerebellar artery aneurysms.
► The video highlights the identification and preservation of the anterior spinal artery.

Video 1  PICA aneurysm; aneurysm clipping; giant aneurysm; cerebrovascular. PICA, posterior inferior cerebellar artery.
