Acute retinal necrosis with central retinal artery obstruction

Prabhjot Kaur,1 Hrishikesh Kaza,2 Avinash Pathengay1

DESCRIPTION
A 58-year-old man with diabetes, hypertension and immunocompetence presented with diminution of vision in the right eye (RE) for 1 week. His best-corrected vision in the RE was hand movements. RE anterior chamber examination revealed three positive cells with keratic precipitates. Significant vitritis with asteroid hyalosis and circumferential large retinitis lesions (figure 1A–C) were noted on fundus examination. There was a cherry-red spot seen hazily at the macula suggestive of an acute central retinal artery obstruction (CRAO). His left eye examination was unremarkable. Optical coherence tomography of the RE passing through the fovea showed the presence of hyperreflective inner layers suggestive of CRAO (figure 1D). A clinical diagnosis of RE acute retinal necrosis (ARN) with CRAO was made and the patient was started on oral valacyclovir (1 g three times per day) with topical steroids. Intravitreal ganciclovir injection with anterior chamber paracentesis under topical anaesthesia was advised due to the extensive retinal involvement and coexisting CRAO. Systemic investigations revealed non-reactive HIV with controlled blood sugars, normal complete blood counts, erythrocyte sedimentation rate and renal function tests.

Within a week of starting therapy with oral valacyclovir and having received two intravitreal ganciclovir injections, there was a reduction in the anterior segment inflammation, vitritis and gradual resolution of retinitis. At 3 weeks, there was further improvement (figure 2A–D) noted along with areas of central clearing in the superior quadrant.

ARN has been associated with central retinal vein occlusion, optic neuropathy, CRAO and CRAO with cilioretinal artery sparing.1–3 Systemic association of HSV meningitis has also been described in association with bilateral ARN with CRAO. It may be prudent to note that these occlusions may develop either prior to the occurrence of retinitis lesions of ARN or simultaneously.3 4  Although extensive vasculitis in patients with ARN has been described, the exact mechanism of the occurrence of occlusive vasculopathy with ARN is unclear.5 However, various authors have proposed the possibilities of direct spread of the virus from adjacent retinitis lesions, spread via sensory nerves or an immunemediated response leading to deposition of inflammatory debris within the vascular wall.6 7 Another risk factor for the occurrence of vascular occlusions with ARN is pre-existing vasculopathy secondary to systemic comorbidities.4 To conclude, in eyes with ARN, increased awareness of the involvement of...
Images in... retinal vessels, including central retinal vessels, is warranted. The involvement of central retinal vasculature in ARN may lead to poor visual outcomes.

Learning points

► Central retinal vascular occlusions, arterial or venous, are rare associations of acute retinal necrosis.
► Prompt treatment with systemic valacyclovir and intravitreal ganciclovir may be warranted in these situations.
► Despite immediate treatment, the visual prognosis remains poor in these cases.

Contributors PK was involved in collection of data, analysis, writing of manuscript and critical review. HK was involved in manuscript review, critical revision and analysis of available literature for formulating the hypothesis. AP was involved in manuscript review, critical revision and analysis.

Funding The authors have not declared a specific grant for this research from any funding agency in the public, commercial or not-for-profit sectors.

Competing interests None declared.

Patient consent for publication Obtained.

Provenance and peer review Not commissioned; externally peer reviewed.
