DESCRIPTION

A 78-year-old man with a known ischaemic cardiomyopathy presented with hypoxaemic respiratory failure and undifferentiated shock. CT head revealed a large middle cerebral artery territory infarct. Transthoracic echocardiography revealed a depressed ejection fraction of 15% and multiple wall motion abnormalities. Multiple thrombi were identified in the left ventricular (LV) cavity with the largest attached to the anterior myocardial segment, measuring approximately 3.6×2.0 cm (figures 1–2, video 1). The patient expired shortly after admission to the intensive care unit.

LV thrombus formation can complicate ischaemic and non-ischaemic cardiomyopathies and result in systemic embolisation. A contemporary study found only 128 cases of LV thrombus out of 140 636 echocardiograms reviewed.¹ The presence of multiple LV thrombi is uncommon.

Virchow's triad describes the factors predisposing to thrombus formation: hypercoagulability, stasis and endothelial injury. The classic substrate for LV thrombus formation is a recent anterior myocardial infarction and an akinetic LV apical segment acting as a nidus for thrombus formation.²

Figure 1 Echocardiogram of the LV in the parasternal long axis view showing a large filling defect consistent with left ventricular thrombus (arrowhead) attached to the interventricular septum (thin arrows). The blood pool is rendered white with the use of contrast for improved endocardial border definition. The large thrombus in the LV appears as a space occupying filling defect or negative contrast. LA, left atrium; LV, left ventricle; RV, right ventricle.

Figure 2 Echocardiogram of the left ventricle (LV) in the parasternal short axis view showing a large filling defect consistent with LV thrombus (arrowhead) at the 1 o'clock position. The anterolateral (AL) and posteromedial (PM) papillary muscles provide a visual comparison for the size of the LV thrombus relative to normal appearing anatomic structures in the LV.

An incidence of 1.6% of patients in a large STEMI (ST-segment elevated myocardial infarction) cohort was diagnosed with LV thrombus post-STEMI with the use of contrast in most of the studies.³ Additional risk factors include severe LV dysfunction, extensive regional wall motion abnormalities and LV aneurysm.⁴

A multimodality imaging approach for the diagnosis of intracardiac thrombi includes echocardiography and cardiac magnetic resonance imaging (CMR). Contrast-enhanced TTE is virtually diagnostic for LV thrombi. Contrast echocardiography in high-risk patients improves the detection of LV thrombus based on anatomic appearance.⁵ Although clinically not absolutely necessary in classic cases, CMR imaging allows tissue characterisation and differentiation from other intracardiac masses.⁵

Major risk factors for systemic embolisation are thrombus mobility, protrusion into the LV cavity, visualisation on multiple views and

Video 1 Transthoracic echocardiography showing depressed left ventricular (LV) ejection fraction of 15% with extensive wall motion abnormalities. Multiple thrombi were identified in the LV cavity. The largest was attached to the anterior myocardial segment and measured approximately 3.6×2.0 cm.

adjacent segments of akinesis and hyperkinesis on echocardiography.^{6,7} Anticoagulant therapy with a vitamin K antagonist is recommended for at least 3 months to reduce embolic complications with a target international normalised ratio of 2.5. Alternative therapy includes the use of direct acting oral anticoagulants which have shown safety and efficacy for the treatment of LV thrombus.⁸ Selected high risk patients can be considered for surgical treatment when the embolic potential is very high or when mechanical circulatory support is required.⁹

Patient's perspective

I know my uncle had heart problems; he just never went to the heart clinic. When they told me he had a massive stroke, I just knew he wouldn't have made it. I wish I checked on him more.

Learning points

- ▶ To highlight the uncommon finding of multiple left ventricular (LV) thrombi and review the classic substrate for LV thrombus formation.
- ▶ To highlight the multimodality imaging approach for diagnosis of intracardiac thrombi.
