Pregnancy with complete heart block

Sasmita Swain, Satyanarayan Routray, Sandhyarani Behera, Swayamsiddha Mohanty

SUMMARY
Pregnancy with complete heart block is rare, its management is not streamlined and requires a multidisciplinary team approach involving the obstetrician, cardiologist, anaesthesiologist and neonatologist. High index of suspicion in a woman with slow heart rate and electrocardiographic examination will ensure the diagnosis of this condition. Such patient can be managed conservatively or may require temporary or permanent pacemaker implantation. We present a 26-year-old primigravida with complete heart block at term pregnancy. She was asymptomatic throughout her pregnancy with pulse rate between 50 and 60 beats per minute. Vaginal delivery was planned under continuous ECG monitoring. Isoprenaline drip and temporary pacemaker were kept stand-by. However, for obstetric reasons caesarean section was performed successfully under spinal anaesthesia without a pacemaker. Method of anaesthesia was planned to keep the haemodynamics stable and drugs causing bradycardia were avoided.

BACKGROUND
Complete heart block (CHB) is an abnormal heart rhythm in which there is no conduction of electrical impulse through the atrioventricular (AV) node, so that there is complete dissociation of the atria and ventricles. The escape rhythm can come from lower focus like AV node, bundle of His, bundle branches or Purkinje fibres. ECG findings of CHB are (1) regular P–P interval, (2) regular R–R interval, (3) lack of an apparent relationship between the P waves and QRS complexes and (4) presence of a greater number of P waves than QRS complexes. The incidence of CHB is estimated to be 1 in 15,000 to 20,000 live birth which may be congenital or acquired. Whenever encountered in a pregnant woman, CHB presents a challenge for the obstetrician and calls for a multidisciplinary approach involving the cardiologist, anaesthesiologist and neonatologist.

CASE PRESENTATION
A 26-year-old primigravida at 38 weeks pregnancy was admitted to Obstetrics and Gynaecology Department of SCB Medical College, Cuttack, Odisha, India for safe confinement. She was referred by her obstetrician for delivery under multidisciplinary guidance in view of associated CHB.

Slow pulse rate (50/min) was detected before her pregnancy, when she consulted a physician for fever in March 2020. ECG revealed CHB with narrow QRS complexes (figure 1). No other organic cardiac problem was detected in echocardiography. She was put on orciprenaline 10 mg two times per day. Apart from fatigue, tiredness and reeling of head in late pregnancy, she had not experienced any dizziness or syncope. She did not have any palpitations, dyspnoea on exertion or chest pain.

She was conscious, oriented with pulse 50 beats/ min regular and blood pressure of 120/76 mm Hg. Her respiratory rate was 18/min and chest was bilaterally clear. First heart sound was variable, second heart sound normal and no murmurs were heard. Uterus was term size, relaxed, with cephalic presentation, left occipito anterior (LOA) position, liquor clinically adequate, vertex 5/5 and fetal heart rate 140 bpm regular.

INVESTIGATIONS
An ultrasound (USG) with Doppler showed a single live fetus of 3 kg with good biophysical profile. All routine laboratory investigations were normal. Serum Na+, K+, Ca2+, Mg2+ were done to rule out any electrolyte imbalances, and were normal. ECG showed CHB with narrow complex QRS. Echo-cardiography did not show any organic cardiac problem.

DIFFERENTIAL DIAGNOSIS
CHB was differentiated from sinus bradycardia by typical ECG findings.

TREATMENT
Orciprenaline 10 mg 8 hourly was continued but pulse rate did not increase and remained at 50/min. During her hospital stay consultation with cardiologist and anaesthesiologist was done regarding her management during delivery vaginal or lower segment cesarean section (LSCS). As everything was normal, we waited for spontaneous onset of labour. However, on completion of 40 weeks and a day patient complained of decreased fetal movement and was very apprehensive. As cervix was not favourable LSCS was planned. The caesarean section was conducted in the morning (routine) hour under spinal anaesthesia in the presence of cardiologist and senior anaesthesiologist. Trans cutaneous pacing pads, isoprenaline drip and temporary pacemaker were kept stand-by. Operation was uneventful.

OUTCOME AND FOLLOW-UP
A full-term normal female child of 3.1 kg with APGAR score 9 nine was delivered. Both mother and baby were healthy and stable at discharge (figure 2) and 6 weeks follow-up.

DISCUSSION
Several physiological changes in cardiovascular system occur during pregnancy to meet the
Case report

increased demands. There is rise in circulatory blood volume, stroke volume, heart rate and a fall in systemic vascular resistance during pregnancy. In CHB heart rate fails to increase and may lead to decompensation particularly during intrapartum and postpartum period. There can be distension of all four cardiac chambers, atria being thin walled are affected most. Thaman et al hypothesise that increased atrial wall stress and structural remodelling can result in increased irritability and conduction delay of atrial musculature. This may result in development of new atrial arrhythmia, unmasking of subclinical conduction abnormality and worsening of clinically evident bradyarrhythmias including different grades of heart block. Resolution of such arrhythmia and conduction delay during the postpartum period in certain situation, strongly support the hypothesis.3

The finding of CHB in pregnancy is rare, if present it is usually congenital. In fact, 30% of the cases of congenital CHB (CCHB) remain undiscovered until adulthood and may therefore present during pregnancy for the first time.1 Acquired heart block during pregnancy is very rare and may be due to myocarditis, collagen vascular diseases like systemic lupus erythematosus, following infective endocarditis of aortic valve with root abscess or as a complication of cardiac surgery. In acquired heart block, block is distal to AV node, heart rate is usually 40 or less per minute with wide QRS in ECG. They are usually symptomatic in the form of black out, presyncope or syncope. CCHB can occur as isolated condition or along with other congenital heart disease. Isolated CCHB is relatively benign, compatible with normal pregnancy, and there may be increase in heart rate with exercise,4 atropine3 or sympathomimetics like orciprenaline as the block is in AV node in such cases. Some patients with CCHB may experience dyspnoea, syncope and Stokes-Adams attacks.5

Symptoms are common in late months of pregnancy, during labour or immediate post partum. During second stage of labour valsalva during bearing down stimulate vagus nerve and may cause dangerous bradycardia, asystole and cardiac arrest. Syncope and cardiac arrest have been reported in postpartum period also. Nakashima et al analysed postpartum cardiac events during 63 pregnancies in 36 women. On multivariate analysis family history of CHB and perinatal ventricular pause was found to be predictors of postpartum cardiac events.7 Our patient was almost asymptomatic except undue fatigue, tiredness and reeling of head. She was detected to have CHB before pregnancy, while consulting physician for medical illness.

Pregnancy outcome

Asymptomatic CHB without organic heart disease usually have favourable pregnancy outcome. However intrauterine growth restriction (IUGR) and preterm birth has been reported in few patients.5 9 Our patient did not have any pregnancy-related complications. In a large series of 21 cases Mandal et al reported oligohydramnios, preterm labour and IUGR in 7%, 11% and 14% of cases respectively.5

Delivery options

There are no definite guidelines for the management of such patients. Vaginal delivery is not contraindicated, caesarean section is reserved for obstetric indications. In the study by Mandal et al, 86% women had vaginal delivery and 14% underwent LSCS for obstetric reasons. Patients with CCHB if asymptomatic, with narrow complex in ECG, ventricular rate (heart rate) between 40 and 60 and there is rise in heart rate with exercise or atropine; usually tolerate the pregnancy and delivery without any unfavourable events.10

Indications for pacing

A pacemaker is indicated if there is history of syncope, wide QRS complex, very low heart rate (less than 40/min), QT prolongation, ventricular dysfunction and heart failure. Permanent pacemaker can be implanted at any stage of pregnancy. Short-term temporary pacing may be required during labour and delivery. In earlier days, temporary pacemaker was used routinely in such patients probably to withstand any haemodynamic alterations. It was seen that many of them did not require pacing and the procedure is not without risk. There can be pacemaker-related radiation exposure, bleeding, embolism, right ventricular perforation, infection or pacemaker malfunction. 2018 European Society of Cardiology Guidelines states that isolated CCHB has a favourable outcome during pregnancy especially with narrow QRS. Temporary pacemaker is unnecessary in stable patients but recommended in selected women with symptoms due to bradycardia and syncope.11

Approach to monitoring

Preconceptional counselling—pregnant woman with CHB and her family members should be counselled for pacemaker implantation, if required during pregnancy.

Antenatal

Patient should be asked about head reeling, black out, syncopal attack and shortness of breath on exertion during her antenatal visit. If such symptoms are there cardiological re-evaluation should be done for readjustment of drugs or need of pacemaker.

Intrapartum

Labour should be monitored and adequate analgesia should be given. Continuous ECG monitoring should be done to detect any life-threatening bradycardia. Instrumental delivery is advocated
to cut short the second stage of labour and to avoid bearing down by the woman. LSCS is done only for obstetric indications. Isoprenalin infusion should be kept stand-by. Femoral/ jugular venous access may be secured for emergency transvenous temporary pacing, if required.

In the centre, where transcatheteraneous temporary pacing is available pacing pads should be attached to the chest wall of the woman, so that immediate pacemaker can be given if required. It will avoid the transfer of patient to catheterisation laboratory.

Post partum
Patient should be monitored in the postpartum period as there is chance of symptomatic bradycardia.

If a temporary pacemaker has been given it has to be removed under the coverage of isoprenalin infusion to avoid the possibility of asystole and cardiac arrest. Such patients may require permanent pacemaker later on and should be followed up.

Contraception
Cafeteria approach with a basket of choices of family planning methods should be offered to the patient as there is no contraindication to any method.

Anaesthetic consideration
There is no clear guideline as regards the appropriate anaesthesia technique in women with CHB undergoing LSCS. Goal is to maintain the haemodynamic stability, technique and drugs chosen should have minimal effect on heart rate. Spinal, epidural and general anaesthesia, with or without temporary pacemaker has been reported in case reports.12-15 Regional anaesthesia is safe in such situation,14 as a stable haemodynamic status can be obtained by titrating intravascular volume and phenylephrine infusion guided by continuous invasive monitoring.12 13 Most authors recommend incremental epidural or low-dose combined spinal and epidural anaesthesia for any instrumental delivery or caesarean section. Our patient underwent caesarean section under spinal anaesthesia without temporary pacemaker support, under cover of oral orciprenaline; with isoprenaline infusion and temporary pacemaker stand-by. We did not encounter any haemodynamic instability probably due to adequate (750 mL) preloading of intravenous fluid. The baby was 3.1 kg with normal APGAR score and without any neonatal heart block or structural heart disease.

CONCLUSION
CHB in pregnancy is rare and it is mostly congenital. One of the common investigation ECG can diagnose CHB. Management of such a grave condition need multidisciplinary team approach. Detailed cardiological evaluation with echocardiography (ECHO) and holter is to be done. Resting pulse rate between 40 and 60, narrow QRS complex in ECG and positive chronotropic response to exercise or atropine in an asymptomatic woman predict a benign course, with uneventful labour and delivery. Vaginal delivery is preferred and LSCS is reserved for obstetric indications. Patient and family members are to be properly counselled. Team of doctors should be prepared to tackle any untoward event.
