Asymptomatic entrapped denture in the hypopharynx

Shogo Hanai,1 Teruhiko Terasawa,2 Mitsunaga Iwata2

DESCRIPTION

An early 70s asymptomatic man with cerebral infarction and dementia was brought to our emergency department for ingesting a removable partial denture. This was seen incidentally on his follow-up chest X-ray, having been diagnosed with aspiration pneumonia provisionally 3 days earlier (figure 1). He did not recall ingesting the denture. His vital signs were normal. There were no abnormal respiratory sounds, such as stridor, wheezing or crackles, heard on auscultation. The 3D-images of the cervix obtained by plain, multidetector CT (MDCT) showed that the denture was in the hypopharynx (figure 2); a laryngeal endoscopy identified the denture in the upper oesophagus, with its metallic clasp entrapped by the postcricoid region. For airway maintenance, tracheostomy was performed, followed by the transoral retrieval of the denture. The clasp was detached from the cervical oesophagus using laryngoscope-guided forceps under local anaesthesia. Pressure ulcers were noted but healed spontaneously as observed by the follow-up laryngeal endoscopy. He was discharged on day 16 of admission.

Foreign body aspiration (FBA) is a potential life-threatening event and typically develops in infants <12 months of age, and occasionally in older adults (>75 years), or in patients with mental disorders regardless of age.1 In adults, dental prosthesis devices such as dental crowns and dentures are a commonly reported cause.1 Adult patients with a small FBA such as a dental crown lodging in the trachea are often asymptomatic or could display only minor symptoms.4 In contrast, symptoms of ingested or aspirated large dentures lodging in the laryngopharynx to upper oesophagus or larynx could vary depending on the impaction sites (table 1).

In the case of large complete or partial dentures lodging in the larynx, typical symptoms include coughing, choking, hoarseness and gagging.1 For instance, a recently reported case of a complete denture aspiration lodging over the oropharynx to laryngopharynx in a cachexic elderly man presented with explicit symptoms including dyspnoea, wheezing, dysphonia and dysphagia.2 Another case of an accidental complete denture ingestion lodging in the upper oesophagus in a woman with schizophrenia and dementia also had symptoms including chest discomfort and pain.3 However, in the present case with an accidentally ingested large partial denture lodging in the laryngopharynx to upper oesophagus, the patient developed fever but did not present with the symptoms described above.

Plain X-rays, a conventional first-line imaging for suspected FBA, may fail to detect dentures made of radiolucent materials such as polymethyl methacrylate, especially when radio-opaque wire hooks are absent.4 Therefore, experts suggest obtaining highly sensitive MDCT-based 3D-images as an alternate imaging option for patients with suspected FBA and presenting typical clinical symptoms.5 MDCT-based 3D-images are also an effective way to triage patients who need rigid bronchoscopy.6 The 3D-MDCT images in our case precisely localised the impacted denture in the laryngopharynx and appropriately guided the transoral retrieval.

In conclusion, foreign body ingestion or aspiration in the laryngopharynx can present very subtle symptoms even when a large denture is the cause.

**Contributors** All authors had access to the data. SH wrote the initial draft. TT and MI revised the manuscript.

**Learning points**

- Foreign body aspiration is a potential life-threatening event and typically develops in infants <12 months of age, and occasionally in older adults (>75 years), or in patients with mental disorders regardless of age.
- Adult patients with a small foreign body aspiration lodging in the trachea are often asymptomatic or display minor symptoms. Foreign body aspiration in the larynx can present very subtle symptoms even when a large denture is the cause.

In conclusion, foreign body ingestion or aspiration in the laryngopharynx can present very subtle symptoms even when a large denture is the cause.
