DESCRIPTION

A 59-year-old man developed sudden onset of chest pain and was admitted to our hospital. Emergent contrast-enhanced CT showed the development of retrograde-type A aortic dissection (AD) with patent false lumen in the descending aorta and thrombosed false lumen in the ascending aorta (figure 1). The patient was treated with intensive drug therapy. We evaluated blood pressure (BP) variability by ambulatory BP monitoring (ABPM), which revealed that the mean BP over 24 h was 150/75 mm Hg with a typical morning surge (figure 2B) despite a combination of several antihypertensive medications for previous 1 month such as amlodipine besilate 10 mg, telmisartan 80 mg, bisoprolol fumarate 5 mg, doxazosin mesilate 8 mg, eplerenone 50 mg, trichlormethiazide 2 mg and methyldopa 50 mg/day. Obstructive sleep apnoea (OSA) has been reported as a cause of drug-resistant hypertension,1 so we performed sleep polygraphic study. This revealed severe OSA with an apnoea-hypopnea index of 56.7/h and lowest percutaneous oxygen saturation of 84% (figure 2A). We started continuous positive airway pressure (CPAP) for the treatment of OSA. Two weeks after the introduction of CPAP, follow-up ABPM revealed a marked decrease in mean systolic and diastolic BP to 126/66 mm Hg (figure 2C). History of hypertension is the most common predisposing factor for AD.2 The presence of OSA is associated with increased risk of incident hypertension, and treatment with CPAP therapy reduces this risk.3 The present case suggested that OSA should be considered in the differential diagnosis of resistant hypertension in the recovery period following dissection. As a specific treatment for OSA, CPAP would assist the

Figure 1 Contrast-enhanced CT illustrates the development of retrograde type A aortic dissection with patent false lumen in descending aorta.

Figure 2 (A) The sleep polygraphic study illustrated the severe desaturation accompanied with obstructive apnoea. (B) The ABPM before CPAP treatment showed uncontrolled high BP. Blue and red dotted lines presented mean systolic and diastolic BP during whole day. (C) The variability of BP after introduction of CPAP treatment illustrated decreased systolic and diastolic BP compared to those before CPAP treatment. ABPM, ambulatory blood pressure monitoring; CPAP, continuous positive airway pressure; BP, blood pressure.
management of drug-resistant hypertension, however CPAP has not yet been proven to reduce the risk of AD. Among patients with AD, OSA should be considered in the differential diagnosis of drug-resistant hypertension, which is a major risk factor for AD.

Competing interests None.

Patient consent Obtained.

LEARNING POINTS
- Obstructive sleep apnoea (OSA) is an important cause of drug-resistant hypertension.
- Continuous positive airway pressure well reduced BP through whole day and achieved well-controlled variability of BP.
- The presence of OSA should be evaluated in the therapeutic strategies of aortic dissection.
- This case describes a link between aortic dissection and OSA.
