DESCRIPTION

The concept of ‘distal driving’ of maxillary posterior teeth has a long orthodontic history.1 Class II malocclusions, which are the most numerous among orthodontic cases, can be resolved by several procedures.1 One involves the distal movement of the maxillary molars to establish class I molar relationships. The premolars and canines are then sequentially moved posteriorly to class I positions, and finally the incisors are aligned and/or retracted.2 This version of the appliance is called ‘Pend-X’. The pendulum springs are so efficient in expanding and rotating the upper first molars that use the Pend-X for 3 or 4 months at the beginning of treatment whenever any expansion or change in anterior arch form is indicated.3 A 13-year-old female patient reported to the department with Angle’s class II division 1 molar relationship, lip strain, convex profile with skeletal class I bases, horizontal growth pattern and incompetent lips because of proclination and increased overjet (figures 1–8). The visual treatment objective was not positive and since the skeletal bases were class I we planned for distalisation. Pendulum appliance was used to distalise the upper molars and class I molar relationship was achieved in 6 months and

10 mm of space was created. The space gained was used in the correction of maxillary anterior proclination and hence correcting the lip strain and improving the lip incompetency. The figures depicts correction of Angle’s class II molar relationship to class I and gaining 10 mm of space by distalising the molars with pendulum appliance (figures 9–16).

**Learning points**

- Molar distalisation is a very good option in non-complaint class II patients.
- Pendulum is a good choice of appliance for molar distalisation.
- With pendulum appliance there is good rotational control.

**Competing interests** None.

**Patient consent** Obtained.

**Provenance and peer review** Not commissioned; externally peer reviewed.
