An interesting science experiment:
hazards of magnets

DESCRIPTION
Abdominal pain is a common problem in children. Although most children with acute abdominal pain have self-limiting conditions, the pain may be an indication of a surgical or medical emergency.1 Diagnoses of acute abdominal pain in children include gastroenteritis, appendicitis, mesenteric adenitis, constipation and very rarely intestinal obstruction.2 The most difficult challenge is making a timely diagnosis so that treatment can be initiated and morbidity prevented.3

A 12-year-old healthy boy was admitted with a 1-day history of sharp colicky central abdominal pain radiating to the right iliac fossa with associated vomiting. His observations were stable and his inflammatory markers were only slightly elevated. An ultrasound scan demonstrated small bowel obstruction with no convincing evidence of appendicitis.

A laparotomy was performed which revealed highly magnetic beads 4 mm in diameter which had caused an ileocaecal fistula (figure 1). The presumed mechanism was a focal pressure necrosis caused by the magnetic attraction of beads in the separate lumens of the caecum and ileum (figure 2). This fistula was sealed with appendices epiploicae from the caecum resulting in small bowel obstruction. The fistula was separated, closed primarily and a thorough washout was performed. Intraoperative imaging was used to ensure all magnets were removed. He was well enough for discharge 6 days later without any postoperative complications.

On further questioning he had accidentally swallowed one then two magnetic beads on consecutive days while at school 2 weeks previously.

Learning points
▸ If the diagnosis is not clear after the initial evaluation, repeated physical examination by a senior physician is often useful.
▸ As a minimum, systematic investigations such as blood tests and plain radiographs should be performed on all children with abdominal pain.
using them as tongue piercings while in a physics class being taught the importance of magnetism.
