DESCRIPTION

Aneurysm of sinus of Valsalva is a rare anomaly which arises from a congenital defect of the aortic media or due to damage caused by bacterial endocarditis. It is more prevalent in men and people of Asian descent.¹

Ruptured sinus of Valsalva (RSOV) is a relatively uncommon cause of acute haemodynamic worsening which is usually seen in young-aged or middle-aged individuals. We present a case of a 23-year-old man who presented with a 20-day history of symptoms of worsening breathlessness; examination showed elevated jugular venous pressure, high volume pulse, S3 and a continuous murmur.

The patient's echocardiogram showed RSOV from the right coronary sinus draining into the right ventricle with *classical windsock deformity* which is usually very uncommon to be seen on transthoracic echocardiogram (TTE; figures 1–3, videos 1–3). He was referred for surgical correction of the defect at another centre where he underwent successful treatment and has been asymptomatic on follow-up.

Definitive diagnosis of RSOV is usually performed with sufficient accuracy using a TTE but sometimes requires a transoesophageal echocardiogram (TEE) or cardiac catheterisation if the echo images are suboptimal or additional lesions need to be defined especially in cases caused by endocarditis. Details of involvement of other coronary sinuses and the extent of involvement and damage to the surrounding structures especially the aortic valve cusps are best obtained by a TEE. Intraprocedural TEE can also facilitate the

performance of percutaneous or surgical closure of defect by assessment of any residual defects after the correction.

The anomaly usually occurs in isolation but may coexist with ventricular septal defect or aortic valve regurgitation in about 30–40% of patients.^{1 2} The most common site of origin of aneurysms is from the right coronary sinus and the most common site of drainage is the right ventricle (70%).

Uncorrected, the rupture almost invariably causes deterioration in heart function and has a rapid downhill course. Early surgical intervention is the treatment of choice as was performed in this case which led to a successful outcome that was maintained at 3 months of follow-up.

Learning points

- ▶ Ruptured sinus of Valsalva (RSOV) is a relatively uncommon cause of acute haemodynamic worsening which is usually seen in young-aged or middle-aged individuals but one of the most common causes of continuous murmur in them.
- ▶ Classical windsock appearance is most commonly seen on transthoracic echocardiogram but it can also sometimes be seen on a transthoracic echocardiogram.
- ▶ RSOV if managed appropriately with surgical correction or device closure can be successfully cured and can have an asymptomatic long-term outcome.
