DESCRIPTION

Infective endocarditis often presents with vegetations attached to the surface of the valve leaflets and sometimes with structural damage of the valves in the form of perforation of the leaflets or in the form of valvular or perivalvular abscesses. Sometimes smouldering infection can damage the valve structure and can cause deformation of the valve structure to such an extent that it conforms abnormal shapes.

We report a rare case of a middle-aged person with a previously undiagnosed atrial septal defect (ASD) who presented with symptoms of progressively worsening exertional fatigue and dyspnoea. The patient had a history of being treated for infective endocarditis by a rare Gram-positive cocci *Gemella morbillorum* which was previously known as *Streptococcus morbillorum*.

The patient was evaluated and found to have severe pulmonary regurgitation and the grossly deformed valve was also causing significant stenosis across the right ventricular outflow tract. The

deformed valve appeared echocardiographically convoluted like a 'cauliflower', which was an interesting echocardiographic appearance (figures 1–3, videos 1–4).

This patient underwent successful replacement of the pulmonary valve with a bioprosthetic valve and patch closure of the ASD. The patient has been stable and asymptomatic after 6 months of follow-up. The occurrence of infective endocarditis affecting the pulmonary valve in a case of ASD is extremely rare with only a few cases which have been reported¹⁻³ and currently ASD does not form an indication for endocarditis prophylaxis.

G. morbillorum is often present as a commensal in the oropharyngeal area. It may rarely cause infections similar to other streptococci which include endocarditis and other invasive infections. A recent study reported it as the most common bacteria present in the teeth with cysts which are not responsive to repeated root canal treatments.⁴ Similar to other streptococci they are usually sensitive to commonly used antibiotics such as penicillin, ampicillin, cephalosporins, tetracyclines, chloramphenicol, macrolide antibiotics and vancomycin.⁵

The occurrence of a grossly deformed valve by a rare organism endocarditis causing severe pulmonary regurgitation makes this case extremely rare and the image interesting.

Learning points

- ▶ Atrial septal defect although not included in the list of lesions requiring infective endocarditis prophylaxis can still be a cause of infection of the pulmonary valve which is subjected to damage due to increased blood flow.
- ▶ Organisms atypical for endocarditis can sometimes be a cause of significant valvular deformity requiring surgery which necessitates a vigorous attempt to culture and accurately identify such organisms.
- ▶ Endocarditis can cause deformation of the valves into abnormal shapes which can form an interesting echocardiographic appearance.
- ▶ Deformed valves can cause haemodynamically significant stenosis and regurgitation simultaneously which can necessitate valve replacement surgery.
