DESCRIPTION

A 38-year-old woman presented to the emergency department subsequent to a high-velocity single vehicle road traffic accident with a fracture of left ulna and radius, right clavicle and sacrum. There was no history of loss of consciousness. Her Glasgow Coma Scale on presentation was 13 and quickly improved to 15. An initial CT brain was normal. On day 4 postadmission she developed rapidly progressive weakness to all four limbs with upper motor signs. An emergent CT brain revealed extensive areas of cerebral infarction bilaterally (figure 1A, B) with an evolving hydrocephalus. A CT angiogram revealed a left internal carotid artery dissection (figure 2B between 2 arrows) and a right vertebral artery dissection (figure 2A The dashed arrow marks the point where the missing right vertebral artery (dashed lines) should join the left vertebral artery to form the basilar artery). An extraventricular drain was sited by the neurosurgeons emergently. She was discharged 9 weeks later mobilising on a Zimmer frame having recovered near complete motor function and a hemianopia on the left.

The incidence of traumatic dissection is thought to be between 2 to 5/1000 with up to 50% having permanent neurological deficits. Those with extracranial dissections can develop a stroke within 24 h but some can occur up to 7 days later. Anyone with

a neurological deficit that is inconsistent with their injuries or with the initial CT brain should be investigated. Trauma patients at a high risk for dissection include those with blunt trauma to the head or neck, cervical or facial bone fractures, those with ischaemic changes on initial CT or the presence of a carotid bruit.^{1 2} Treatment varies with each patient but is primarily medical with anticoagulation and antiplatelet therapy. Anticoagulation is associated with a high risk of intracranial bleeding. Endovascular stenting is an option for those who are unsuitable for medical treatment.^{1 2}

Learning points

- ▶ Patients with an extracranial dissection can develop the symptoms of a stroke within 24 h of the injury, however, some may develop symptoms up to 7 days later.
- ▶ Those with blunt trauma to the head or neck, cervical or facial bone fractures, those with ischaemic changes on initial CT or the presence of a carotid bruit are at risk of dissection.
- ▶ Close monitoring, early recognition and prompt treatment confer better outcomes in what is otherwise a devastating scenario with high risk of morbidity and mortality.
