DESCRIPTION

While peripheral artery aneurysms are rarely encountered, brachial artery aneurysms are even rarer. Most of those seen are usually dissecting aneurysms of infectious, post-traumatic or iatrogenic origin; true aneurysms of the brachial artery are even more unusual.^{1,2} There may be a cause of in situ thrombosis, which might occlude vessels. The risk of limb loss can be avoided by prompt diagnosis and early surgery.^{3,4} The best therapeutic option is operative repair or closure by covered stent, although there are no uniform guidelines regarding the timing and indications of intervention.

We present an interesting case of a 58-year-old man who presented with symptoms of atypical chest pain with non-specific ST-T changes in the ECG. The patient was taken up for a diagnostic angiogram from the right radial access but difficulty was experienced in negotiating the wire across the brachial artery. The wire took an unusual loop in the brachial artery (figure 1 and video 1); the check shot taken showed a large brachial artery aneurysm (figures 2 and 3, videos 2 and 3). The coronary angiogram subsequently performed revealed insignificant coronary artery disease.

The patient was planned for conservative management for the coronary artery disease and since the aneurysm was incidentally detected, the patient was given the option of surgical correction or percutaneous treatment with covered stent. The patient opted for conservative management.

The patient was asymptomatic at 3 months of follow-up.

The aetiopathogenesis of aneurysms is multifactorial with a definite role of genetic predisposition working hand in hand with risk factors that are mostly similar to those for atherosclerosis, such as smoking, hypertension and dyslipidaemia, in association with others such as copper deficiency and tertiary syphilis.⁵ This patient had none of these risk factors and no family history of aneurysms or coronary artery diseases. The coronary arteries had

evidence of mild atherosclerosis, which might have played a part in this.

Prevention of aneurysm formation and enlargement includes control of risk factors, while drugs such as β -blockers and losartan have shown some benefit.^{6,7} There are no clear guidelines for the management of incidentally detected and asymptomatic peripheral artery aneurysm in contrast to aortic aneurysm.

For most cases of giant aneurysms, surgical therapy forms the standard of care, although in appropriately selected cases covered stent is a reasonable alternative. There have been a series of successes of covered stents in peripheral aneurysms but higher incidence of stent thrombosis has been reported.⁸

Learning points

- ▶ Peripheral artery aneurysms are rare and usually found incidentally. They may be observed clinically in the form of unusual pulsations or as an abnormal pulsatile swelling. Rarely, the first presenting symptom could be pain, thrombosis or acute rupture. Idiopathic aneurysms are rarely seen.
- ▶ There are no specific guidelines for their management and no clear cut-off size or symptom level for an intervention to be undertaken.
- ▶ Corrective surgery or percutaneous closure using covered stents are acceptable treatment options in management of such cases. Long-term follow-up and the incidence of recurrence may be variable with respect to the aetiology and success of correction.

Competing interests None.
