FDG positron emission tomography of giant cell arteritis with polymyalgia rheumatica

Kiyoshi Shikino, Masatomi Ikusaka, Fumio Shimada

DESCRIPTION
An 80-year-old woman presented with low-grade fever, weight loss and shoulder ache persistent over 6 months. She had developed headache with scalp allodynia, though these had improved spontaneously within 2 months. Physical examination revealed an absent temporal artery pulse and decreased range of active shoulder motion. Laboratory findings showed a high erythrocyte sedimentation rate (73 mm/h). Temporal artery ultrasonography revealed no halo sign, stenosis or occlusion. Fluorodeoxyglucose positron emission tomography (FDG-PET) showed increased uptake in the thoracic aorta and carotid and subclavian branches, and bilateral shoulder, hip, and interspinal regions in the lower thoracic and lumbar spine (figures 1 and 2). Giant cell arteritis (GCA) with polymyalgia rheumatica was diagnosed. Symptoms improved with prednisolone (30 mg/day).

GCA is associated with chronic vasculitis of large vessels, primarily the aorta and its main branches. It occurs in individuals aged >50 years. Polymyalgia rheumatica is closely linked to GCA, occurring in about 40–50% of patients. Headache is present in 90% of cases, frequently accompanied by scalp allodynia. In some cases, the inflammatory process may

spontaneously become clinically silent,\textsuperscript{1} requiring clinicians to evaluate symptoms by direct questioning.

Temporal artery ultrasonography, one of the non-invasive tests, is helpful in diagnosing giant-cell arteritis (sensitivity 88% and specificity 78%).\textsuperscript{2} FDG-PET can be used to detect subclinical inflammation of large vessels in GCA.\textsuperscript{3} Although there is no perfect method for the diagnosis of GCA at present, FDG-PET may play a role in the management of GCA when the ultrasonography is negative.

Learning points

- Headache is present in 90% of giant cell arteritis (GCA) cases, frequently accompanied by scalp allodynia.
- The inflammatory process may spontaneously become clinically silent, requiring clinicians to evaluate symptoms by direct questioning.
- Fluorodeoxyglucose positron emission tomography may play a role in the management of GCA when the ultrasonography is negative.
