DESCRIPTION

A 71-year-old man with long-standing type 2 diabetes mellitus was admitted for optimisation of glucose control. His antihyperglycemic medication comprised metformin, glimepiride and insulin glargine at bedtime. He also reported mildly impaired cognitive function and short-term memory. On physical examination, numerous well-defined erythematous spots, telangiectasis and striae distensae, spread over the abdomen, were detected (figures 1 and 2). Differential diagnosis included skin changes due to a glucagonoma, hypercortisolism or another acquired vascular lesion of the skin. Laboratory evaluation yielded glycated haemoglobin (HbA1c) of 8.6%, a physiological dexamethasone suppression test and a normal urinary cortisol excretion; plasma glucagon concentration was within the reference range.

Thorough medical history taking revealed a car accident 4 years earlier and that the skin changes appeared thereafter. Skin biopsy showed ectatic dilated capillaries in the superficial dermis (figure 3) and in the context of the car accident a diagnosis of

Figure 2 Higher magnification of figure 1 showing numerous well-defined erythematous spots and telangiectasis.

acquired Port-wine stain (PWS) (nevus flammeus, Fegeler syndrome) was made.

PWS are vascular malformations with normal endothelial cell cycles and are most often congenital. Acquired forms of PWS are morphologically indistinguishable from congenital PWS.¹ It is suggested that the histopathological features consisting of dilated, ectatic capillaries arise from malformed sympathetic innervation. A preceding trauma is among the most frequent causes of acquired PWS.^{1–3} Pathogenetically, it is assumed that traumatic injury of the skin induces perivascular atrophy leading to vessel dilation or that impaired reparative processes in vessels result in dilated vessel walls. Cases of non-trauma-related PWS have been described in conjunction with the intake of isotretinoin,⁴ oral contraceptives, simvastatin and metformin.

Learning points

- ▶ Port-wine stains (PWS) are vascular malformations usually present at birth. Acquired PWS are infrequently reported in the literature and have mostly been attributed to mechanical trauma. Trauma-related PWS are also called *Fegeler syndrome*, named so after Fegeler, who first described a case of a trauma-related PWS.
- ▶ Dermatological examination reveals well-defined erythematous macules. Histologically, these changes refer to dilated, ectatic vessels.
- ▶ Laser (especially pulsed dye laser) is the treatment of choice. Acquired PWS tend to better respond to treatment than congenital PWS.

Acknowledgements The authors would like to thank PD Katrin Kerl French, Division of Dermatology, University Hospital Zurich, for performing the histological analysis.

Contributors YN-O was responsible for collecting the patient data/material and writing the manuscript. GS was responsible for revising the manuscript.

Competing interests None declared.

Patient consent Obtained.

Provenance and peer review Not commissioned; externally peer reviewed.
