DESCRIPTION

A 59-year-old man with obsessive compulsive disorder (OCD) was on antidepressant treatment for years. Six months ago, he got a severe headache on the left side of his head, reported pain behind his left eye, diplopia and ptosis displayed on his left eyelid. The patient had mild migraine attacks occasionally. However, his previous headache was very intense when compared with earlier ones. By cranial MRI, a lesion (22×7 mm horizontally, 13×8 mm vertically) adjacent to carotid segment 4 (C4) of the left internal carotid artery was found. The lesion showed a hyperintense signal in contrast-enhanced T2-weighted images, which was the result of enhanced abnormal soft tissue extending through the orbital fissure and into the orbital apex. This did not cause compression on the optic nerve and there was slight bulging into the left cavernous sinus (figure 1). The patient's blood and cerebrospinal fluid biochemical parameters were within normal limits. An aneurysm was found in the ascending aorta with a width of 4.5 cm (normal width=2.5 cm) and followed-up for further risk of dissection.

The patient was diagnosed with Tolosa-Hunt syndrome (THS), and he was started on prednisolone 64 mg/day. Periorbital pain, diplopia and left eyelid ptosis disappeared after 2 months of high-dose cortisone treatment.

THS is an episodic, painful ophthalmoplegia of unknown aetiology, involving ipsilateral paralysis of one or more of the third, fourth and sixth cranial nerves and the ophthalmic and/or maxillary branches of trigeminal nerve. There is inflammation in the cavernous sinus or the superior orbital fissure. Severe orbital and periorbital pain usually starts prior to paralysis of cranial nerves. Symptoms improve rapidly with corticosteroid treatment.¹ THS is diagnosed according to the criteria defined by International Headache Society Classification, 2004. MRI findings are important for clarifying the diagnosis.² The incidence of THS is estimated to be 1–2 cases per million people.³

Vascular malformations and deformities involving intracranial arteries have been reported in some cases of THS. Zhou *et al*⁴ reported a case of dissection aneurysm of the internal carotid artery; the suggested cause was inflammation related to THS. In another case, a mycotic abdominal aortic aneurysm was found to be associated with THS.⁵ None of the reported cases had comorbid psychopathology. In our patient, the aneurysm in the ascending aorta may have been caused by inflammation.

Proinflammatory markers have been reported to be elevated in children and adolescents with OCD.⁶ For example, in patients with paediatric autoimmune neuropsychiatric disorders associated

Figure 1 MRI findings of a male patient with left-sided Tolosa-Hunt syndrome. (A, B and D) Axial T1-weighted, (C) axial T2-weighted, (E) sagittal T1-weighted, (F) sagittal T1-weighted sequences showing an enlarged left cavernous sinus (black arrows). (C) Axial postcontrast T2-weighted sequence showing the enhancement of the soft tissue.

with streptococcal infection (PANDAS), OCD occurs due to autoimmune-mediated inflammation of the basal ganglia triggered by the streptococcal infection.⁷

Inflammation may be the common factor underlying the pathology of THS, OCD, and the aortic aneurysm in our patient. Therefore, the symptoms of our patient may be components of a yet undefined clinical syndrome with either an immune or genetic basis. For example, the patient might have an undiagnosed or as yet undefined connective tissue disease with neurovascular manifestations.⁸ Antidepressants have neuromodulatory effects and are commonly used in the management of autoimmune diseases; however antidepressant drug-related autoimmune reactions contribute as well.

In our search of literature, we have not found any other cases of THS comorbid with OCD and aortic aneurysm. This comorbidity may be a coincidence, an undefined new syndrome

or an atypical presentation of a known disease. We also suggest that whole body vascular pathology shall be assessed in patients with THS.

Learning points

- Tolosa-Hunt syndrome (THS) is a rarely seen, episodic and painful ophthalmoplegia and MRI plays a very important role in clarifying the diagnosis of THS.
- THS symptoms disappear rapidly through steroid treatment.
- Echocardiography is to be performed because of the possibility of an aortic aneurysm.
