Melphalan-induced cardiotoxicity: ventricular arrhythmias

U Yanamandra, S Gupta, A Khadwal, P Malhotra

DESCRIPTION

A 61-year-old man, with multiple myeloma (IgA lambda), was planned for autologous stem cell transplantation (ASCT). He also suffered a left thalamic haemorrhagic stroke in 1998 secondary to aneurysmal bleed. Following melphalan infusion of 200 mg at 45 mL/min, he developed acute onset rhythm abnormalities (intermittent ventricular ectopic and ventricular tachycardia). The patient’s premelphalan evaluation was unremarkable with

Figure 1 (A) Normal ECG before starting melphalan infusion. (B) ECG after 200 mg of melphalan infusion, showing acute onset ventricular rhythm with atrio-ventricular (AV) dissociation. Subsequent ECG showing dynamic ventricular rhythm at (C) 4 hours (D) 8 hours and (E) 12 hours postinitiation of melphalan infusion. (F) Normalisation of rhythm after 18 hours postinitiation of melphalan infusion.
normal ECG (1A), ejection fraction (55%) and renal/hepatic function. He was evaluated by sequential 2D echocardiography and troponin I (immediately, 2, 4, 12 and 24 hours) which were normal excluding acute STEMI. These rhythm abnormalities were dynamic probably secondary to the plasma melphalan concentrations and normalised by 18 h postinfusion (figure 1B–F). There has been no recurrence of these rhythm abnormalities thereafter. He was transplanted with abbreviated melphalan conditioning.

Cardiac toxicity in the form of atrial fibrillation (AF, 6.6–11%) and supraventricular tachycardia are common after high dose melphalan. Melphalan is considered the most arrhythmogenic chemotherapeutic agent used in ASCT. Increased age (>60 years), higher baseline creatinine, larger left atrium size and previous cardiac comorbidities are noted risk factors for supraventricular tachycardia (SVT), of which our patient only had age as a risk factor. Other conditioning drugs in ASCT with similar cardiotoxicity include cyclophosphamide, anthracyclines and fludarabine. The presence of amyloidosis in multiple myeloma (MM) increases the risk of arrhythmias during ASCT conditioning. Investigators used amifostine to counter cardiac toxicity of increased dose melphalan (~280 mg/m2). We present this case due to the rarity of ventricular arrhythmias secondary to melphalan and reversal of normal rhythm chronologically coinciding with excretion $t_{1/2}$ of the drug.

Acknowledgements The authors thank Dr Ganesh Kasinadhuni, Cardiology senior resident, for evaluating the case from cardiology department.

Contributors UY, SG, AK and PM involved in the management of the patient. UY involved in the manuscript preparation. All authors vetted the submitted manuscript.

Competing interests None declared.

Patient consent Obtained.

Provenance and peer review Not commissioned; externally peer reviewed.
