Shoulder pain in smokers could be a life changer
Ahmed Sayeed, Fayez Mobarak Mohammed Alshamrani, Abdullah Yahya Amrayn, Abrar Alharbi

CASE HISTORY
A 51-year-old Saudi man presented to us with a 4-week history of right shoulder and chest pain radiating to the back. He also had distal and proximal muscle weakness of the right upper limb.

He is a chronic smoker for 40 years, about three packs per day. His lifetime exposure to tobacco was 120 pack years. He lost about 3 kg in the last 1 week. There was no history of cough or shortness of breath or fever with night sweats.

He had a history of pulmonary tuberculosis 28 years ago and taken complete treatment for 1 year.

On examination, there was ptosis, enophthalmos, narrowing of palpebral fissure and miosis of the right eye and anhidrosis of the right half of the face (figure 1). He also had clubbing of fingers.

The motor system examination of the right upper limb showed grade 3 plus power and weak hand-grip.

The chest examination showed decreased movement with impaired note and reduced intensity of breath sounds on the right upper half of the chest.

The chest X-ray showed a right apical lobe mass with clear evidence of volume loss on right lung and this finding was confirmed on CT chest, which also showed a right apical lobe mass (figure 2).

He underwent bronchoscopy with bronchealveolar lavage, which showed squamous cell carcinoma.

A diagnosis of a Pancoast tumour caused by a right apical mass due to squamous cell carcinoma was made.

He has undergone staging CT scan and is being planned for chemotherapy.

DISCUSSION
Pancoast tumour is defined as a tumour which invades any structures of the apex of the chest like first rib, brachial plexus, sympathetic chain and stellate ganglion near the apex of the lung.1

The aetiology is based on the site of lesion and the site involved. It is divided into central, preganglionic and postganglionic. The central causes are stroke, tumour and denuemelination. The preganglionic causes are subclavian artery aneurysm, Pancoast tumour and iatrogenic trauma. The postganglionic causes include trauma, iatrogenic neck dissection and tumours.2

The Pancoast tumour usually presents with shoulder pain due to invasion of the brachial plexus or parietal pleura. The diagnosis is usually obtained by ultrasound or CT-guided core biopsy of the apical tumour.

The treatment depends on the stage of the disease. The induction chemotherapy followed by surgery results in better survival rate. The surgery is undertaken after 5 weeks of chemotherapy and it involves enbloc resection of the tumour and the chest wall along with other involved structures like sympathetic ganglion, stellate ganglion and so on.3

Learning points
► Shoulder pain in smokers could be a symptom of Pancoast tumour.
► Chemotherapy with radiotherapy followed by surgery is the treatment of choice for Pancoast tumour.
