DESCRIPTION

A 47-year-old woman was diagnosed with systemic lupus erythematosus (SLE) at age 27 based on articular involvement (Jaccoud's arthropathy), lymphopaenia, thrombocytopaenia, pleuritis and positive antinuclear/anti-dsDNA antibodies. She was under azathioprine 75 mg and mycophenolate mofetil 3 g daily. Renal involvement (diffuse proliferative glomerulonephritis) was diagnosed 2 months ago. She was admitted with a 2-week history of diarrhoea, abdominal pain and intermittent fever. Physical examination revealed lower abdominal discomfort and mild bilateral leg oedema. Laboratory analysis showed severe hypoalbuminaemia, pancytopenia, elevated C reactive protein (25.8; $n < 0.5$ mg/dL) and normal coagulation tests. She had active disease Systemic lupus erythematosus disease activity index of 23 (SLEDAI-23), starting prednisolone 1 mg/kg/day and 5-day course of intravenous immunoglobulin 2 g/kg/day; mycophenolate mofetil dose was reduced (2.5 mg/day). Infectious disease screening was negative, including cytomegalovirus (CMV) (IgM-/IgG+, negative serum CMV-DNA). Ileocolonoscopy showed a colorectal congestive/granular mucosa with erosions, friability and subepithelial haemorrhagic suffusions (figure 1A–C). Biopsies revealed normal ileal mucosa and SLE-related pancolitis

Figure 2 Histopathology of colonic biopsy specimens showing ischaemic and inflammatory subacute colitis with polymorphonuclear infiltrate (neutrophils and eosinophils), intense apoptosis, glandular necrosis and acute vasculitis, compatible with systemic lupus erythematosus-related colitis (A,B); biopsies from the base and edge of colonic ulcers revealed cytomegalovirus-positive cells by immunohistochemical staining (C,D).

Figure 1 Endoscopic appearance of systemic lupus erythematosus-related colitis with a congestive and granular mucosa with friability, diffuse erosions and subepithelial haemorrhagic suffusions throughout the colon and rectum (A,B,C), and subsequent colonoscopy with several cytomegalovirus-positive ulcers along the colon (D).

(figure 2A,B). However, she worsened with febrile neutropaenia, increasing inflammatory parameters and chronic renal disease without exacerbation or oligoanuria. Infectious disease rescreening, including blood and urine cultures, was negative. Chest and plain abdominal X-rays were normal. Broad-spectrum antibiotics, 3-day course of intravenous methylprednisolone 500 mg, ciclosporin 150 mg/day and filgrastim were added. Two weeks after admission, despite improvement in inflammatory parameters, she developed intermittent haematochezia with haemodynamic instability requiring daily blood components transfusion. Oesophago-gastroduodenoscopy was normal. Colonoscopy was repeated showing vasculitis and several ulcers throughout the colon (figure 1D), the biopsies of which revealed CMV-positive cells (figure 2C,D). CMV serology was repeated with negative IgM, but elevated CMV-DNA (5 693 532 copies/mL), starting intravenous ganciclovir 5 mg/kg/day. She continually worsened with severe anaemia (haemoglobin: 4–5 g/dL). Additional coagulopathies study was negative without evidence of disseminated intravascular coagulation. CT angiography showed mild diffuse colorectal wall thickening but no evidence of focal active bleeding, small bowel

Learning points

- Systemic lupus erythematosus (SLE)-related colitis represents a rare and potentially life-threatening condition. This disease should be suspected in a patient with LES presenting with abdominal pain, diarrhoea and lower gastrointestinal bleeding.
- Endoscopy and histopathology are essential in SLE-related colitis diagnosis and the exclusion of superimposed conditions, including cytomegalovirus infection.
- Early diagnosis and prompt treatment are crucial to improve prognosis.

abnormalities or mesenteric vessels thrombosis. After the multi-disciplinary team meeting, she underwent total proctocolectomy with terminal ileostomy. Histopathology of surgical specimen revealed a diffuse colorectal ischaemia and vasculitis compatible with SLE-related colitis with CMV superinfection. Due to bleeding from stoma, she was relaparotomised with resection and reconnection of ileostomy, with cessation of bleeding. The resected specimen revealed ischaemic ileostomy with normal ileal mucosa upstream of ileostomy, without involvement of surgical margins. Unfortunately, she died 1 day after proctocolectomy.

SLE represents an autoimmune inflammatory disease with multisystem involvement. Gastrointestinal symptoms are common in patients with SLE, often related to adverse drug reactions and infection.¹ SLE-related colitis, as a consequence of

lupus mesenteric vasculitis, is a rare (0.2%–9.7%) and potentially life-threatening condition.^{1–3} Despite improvement with corticosteroids and immunosuppressive agents,^{1,2} there is an increased risk of serious superimposed infections as CMV infection.^{1,3} We present the case of a fatal lower gastrointestinal bleeding caused by colitis associated with active SLE and complicated by CMV colitis despite immunosuppression intensification, target therapy for the identified infection and salvage proctocolectomy. Endoscopy and histopathology are essential in SLE-related colitis diagnosis and superimposed infection exclusion. Early diagnosis and prompt treatment are crucial to improve prognosis.

Contributors EG-S and MG-S contributed equally, writing the manuscript and reviewing the literature. EG-S is the article guarantor. MAC reviewed histopathological findings. PA critically reviewed the manuscript.
