Asymptomatic dysphagia causing recurrent aspiration pneumonia

Anders Løkke,1 Lycely Calderon Dongo,1 Karin Bak Aksglæde,2 Ole Hilberg3

SUMMARY
52-year-old male patient with known bipolar disorder and innate cerebral palsy causing widespread spasticity problems. Treated for 2 years with antidepressants and electroconvulsive therapy. He repeatedly presented with—pneumonia resulting in more than 20 episodes of hospital admission. He underwent numerous examinations until a diagnosis of dysphagia was established using video fluoroscopic swallowing examination (modified barium swallow). Eventually, as all other treatment regimens had proven effortless, percutaneous gastrostomy feeding tube was inserted and intensive training with a specialised occupational therapist was started. This treatment regimen caused the recurrent episodes of pneumonia to vanish. It is important to acknowledge that otherwise silent dysphagia may cause recurrent pneumonia.

BACKGROUND
Pneumonia is a very common condition that most doctors face frequently, and normally it is rather easy to treat. However, when a patient presents with recurrent pneumonia, it is time to pause and consider why—including age and expositions into considerations.

It is important to note that in many cases, swallowing disorders may occur in the absence of symptomatic dysphagia. Silent aspiration may occur when the patient is unaware and there are no signs of obstruction such as coughing. As a result, aspiration is often overlooked and silent dysphagia may cause recurrent pneumonia.

CASE PRESENTATION
A 52-year-old man with known congenital cerebral palsy causing widespread spasticity problems, swallowing dysfuction and bipolar affective mental disorder. He was treated with phenytoin, carbamazepine and baclofen.

Due to personality and behavioural disorder, depressive traits and self-harm, the patient was admitted to the psychiatric department 15 times in 2012 and 14 times in 2013 and was treated with electroconvulsive therapy (ECT) 12 times in 2013.

In 2014, he had 22 contacts to the emergency department due to pneumonia.

Suspected asthma led to treatment with inhalation medication without effect. Immunodeficiency disorder was ruled out.

Bronchscopy was macroscopically normal, negative microbiological growth.

Walking test and lung function test were normal.

Referred to occupational therapist in February 2015 for swallowing test without signs of dysfunction. However, strength, muscle tone and coordination of the tongue were found to be reduced.

A video fluoroscopic swallowing examination (VFSE), also called modified barium swallow, in April 2015 showed ‘profound tendency of retention in vallecula and silent aspiration’.

A nasogastric feeding tube was placed tentatively, resolving the recurrent episodes of pneumonia immediately. In August 2015, a percutaneous gastrostomy feeding tube was placed and intensive training with a specialised occupational therapist was initiated—primarily involving training of the swallowing function, the strength of the muscles in the tongue and the throat as well as paying much attention when drinking and eating. The patient started off with nothing per os for a month, followed by very slow introduction of fluid and solid food over a course of several months (case time course shown in table 1).

INVESTIGATIONS
► Otoshinolaryngologist, flexible laryngoscopy.
► Neurological evaluation.
► Psychiatric medicine adjustment, electroconvulsive therapy.
► Respiratory physician evaluation.
► Immunodeficiency evaluation, HIV test.
► Bronchscopy.
► High-resolution CT.
► Six-minute walking test.
► Lung function test.
► Specialised occupational therapist evaluation.
► VFSE×3.

DIFFERENTIAL DIAGNOSIS
► Tracheo-oesophageal and tracheopulmonary fistulas.
► Foreign bodies.
► Infections.
► Obliterative bronchiolitis.

TREATMENT
Multidisciplinary teamwork:
► Specialised occupational therapist.
► Gastroenterology surgeon.
► Respiratory physician.
and treatment with neuropsychiatric medication—was admitted and psychiatric disorders as well as gastrointestinal symptoms—was admitted and psychiatric disorders as well as life-threatening.

A patient with cerebral palsy. The result can be devastating as mental state resulting in admission due to depression the pneumonia episodes as well as the deterioration of drastic, but the time course, the number and severity of intense occupational therapist training may seem rather.

Numerous solutions were tried, including sleeping with the head elevated, reduction in the neuropsychiatric medication as prophylactic antibiotics with azithromycin.

Aspiration can be silent and thus easily overlooked. The possibility of a swallowing aspiration in patients with recurrent episodes of pneumonia should be considered.
