DESCRIPTION

A preterm baby born at 32 weeks of gestation with a birth weight of 1.4 kg referred to us on day 11 of life with feed intolerance and scrotal swelling. Examination revealed slightly distended abdomen, absent bowel sounds and a huge scrotal swelling which was soft in consistency with shiny skin (figure 1A) and brilliant transillumination (figure 1B). Abdominal radiograph showed air under the right dome of the diaphragm (figure 1C, white arrows) and hugely distended scrotum with gas which was extending up to the inguinal canal (figure 1C, yellow arrows). He was managed as a case of necrotising enterocolitis (NEC) with intravenous antibiotics, nil per oral, gastric aspiration and primary peritoneal drainage (peritoneal drain for 7 days). There was an improvement in abdominal distension, feed intolerance and scrotal swelling (figure 1D); and resolution of air under the diaphragm, and pneumoscrotum (figure 1E). He was discharged after a hospital stay of 14 days.

Pneumoscrotum is defined as the accumulation of air in the scrotum. It is uncommonly reported in neonates.^{1–3} Air may reach the scrotum by one of the three mechanisms: intraperitoneal air (after gut perforation, referred as scrotal pneumatocoele); extraperitoneal air from lungs, mediastinum or retroperitoneum dissecting through fascial planes into the scrotal wall; and local scrotal causes (trauma, gas gangrene).^{1–3} An inguinal hernia is one of the differentials of brilliant transillumination in the scrotum, but the clinical presentation made us to think of pneumoscrotum. In neonates, pneumoscrotum is commonly due to

bowel perforation, as in index case.¹ The diagnosis of pneumoscrotum is clinical (inspection and palpation of the scrotum). The radiograph helps in identifying the presence of air in scrotum and determining its origin (peritoneum or thorax). Pneumoscrotum is an important radiographic sign to aid in the diagnosis of bowel perforation especially in neonates and infants. Pneumoscrotum is usually found along with other signs of pneumoperitoneum. Pneumoscrotum per se is a benign medical condition, but the cause of it needs to be identified and treated appropriately based on the primary aetiology and physiological status of the patient.³

The index preterm neonate had NEC and intestinal perforation. The reason for pneumoperitoneum is possibly due to the passage of air from peritoneum to scrotum through patent processus vaginalis (which is patent in 80%–95% of newborn males) that caused gaseous distension of scrotum.¹ Pneumoscrotum was the predominant sign of intestinal perforation in index preterm neonate with NEC which resolved with treatment.

Learning points

- ▶ Pneumoscrotum may be the sole obvious manifestation of bowel perforation in preterm neonates and is an important radiographic sign to aid in diagnosis.
- ▶ Every effort should be made to find out the site of air leak in a neonate presenting with pneumoscrotum.

Acknowledgements The authors thank Renu Suthar for critically reviewing the case report.

Contributors SKA: supervised patient management and manuscript writing. RPK: surgical management of patient. GP: patient management. VS: supervised patient management.

Funding The authors have not declared a specific grant for this research from any funding agency in the public, commercial or not-for-profit sectors.

Competing interests None declared.

Patient consent Parental/guardian consent obtained.

Provenance and peer review Not commissioned; externally peer reviewed.
